# 1 Task 1: Polynomial Curve Fitting for Dataset 1

## 1.1 Training Dataset of size 10

### 1.1.1 Plots of Approximated Functions without Regularization

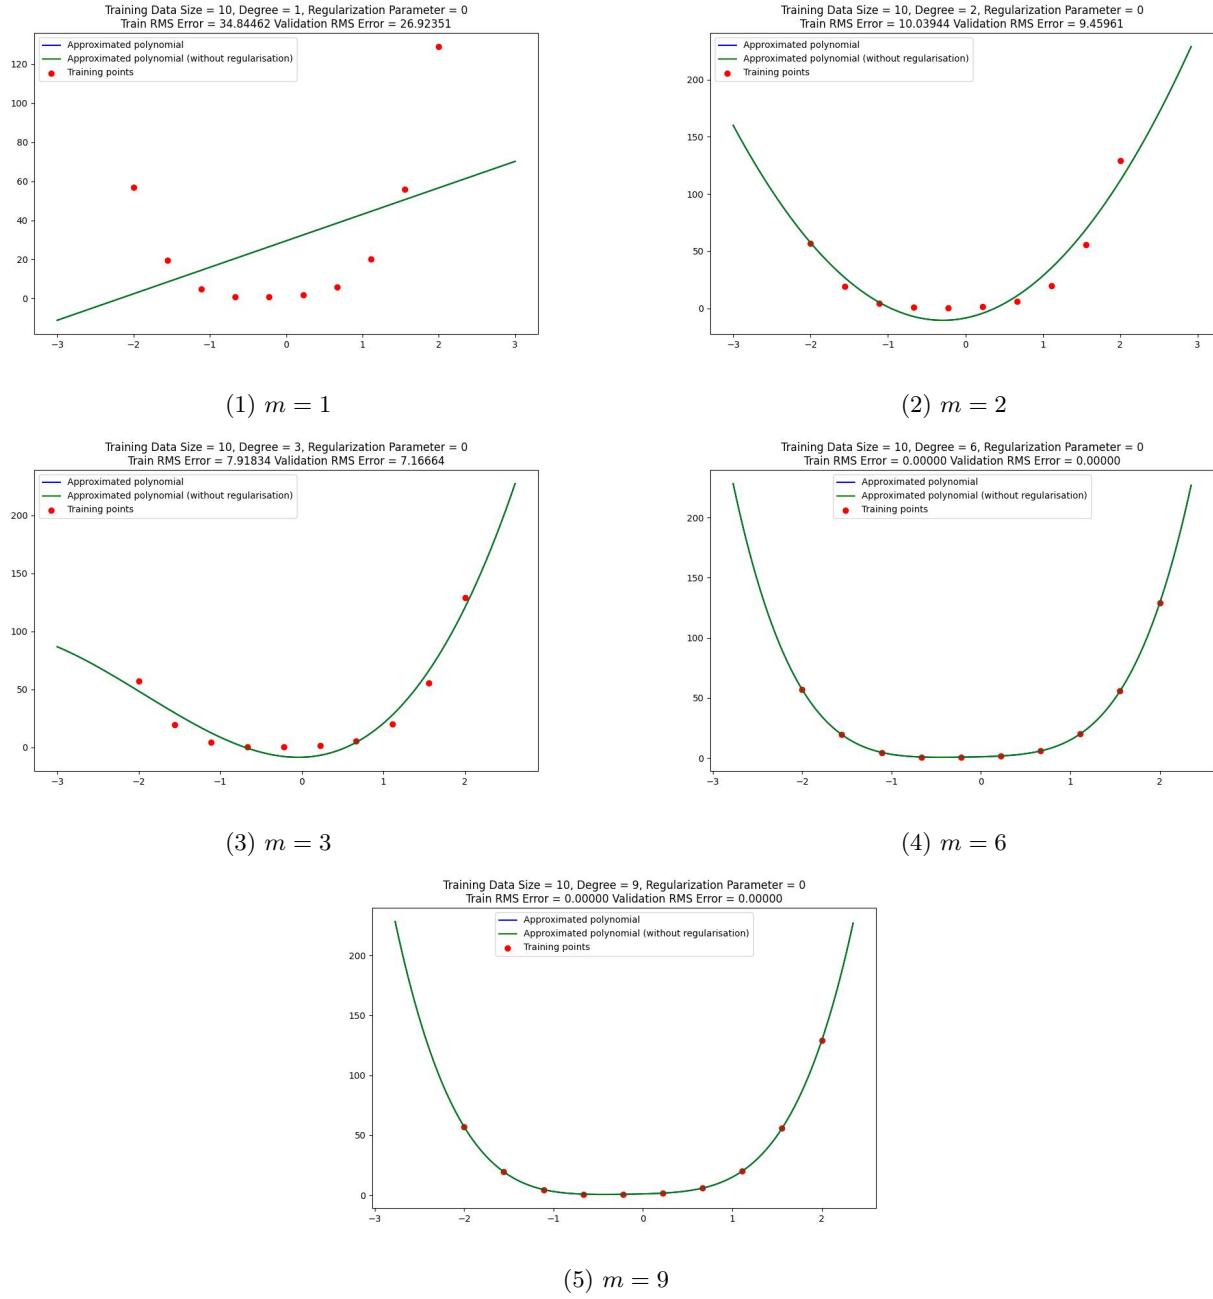

Figure 1: Approximated Functions without Regularization for training dataset of size 10

### 1.1.2 Inferences

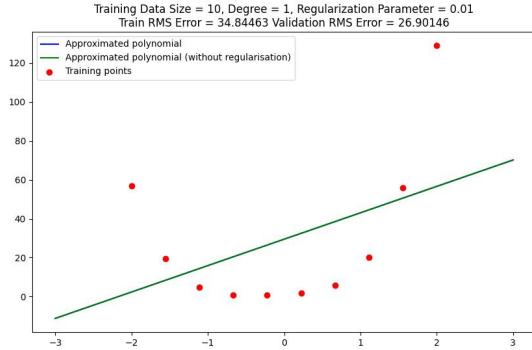

- With small values of degree  $m$  such as 1, 2 and 3, the approximated model is unable to fit to the training data accurately. Both the training and validation errors are large. This is a case of underfitting. This indicates that the underlying distribution of the data has a higher complexity than expected.
- With large value of degree  $m = 9$ , the approximated model fits exactly onto the training dataset. But this can be a case of overfitting as there are only 10 data points available. The number of parameters to estimate is given by

$$D = \frac{(m + d)!}{m! \cdot d!}, m = \text{degree of polynomial}, d = \text{dimensionality of input vector} \quad (1)$$

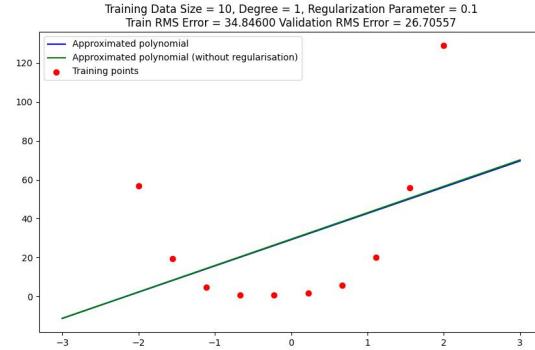

which with  $m = 9$  and  $d = 1$ , gives 10 parameters. So, we need much more than 10 datapoints to train this model effectively. Hence, this is not the best model possible.

- With degree  $m = 6$ , the approximated model fits exactly onto the training data and the number of datapoints is sufficient to train this model. Hence, this model gives the best result with the given training points. Since this model has nearly zero training and validation error, we don't require the use of regularization to improve the model.

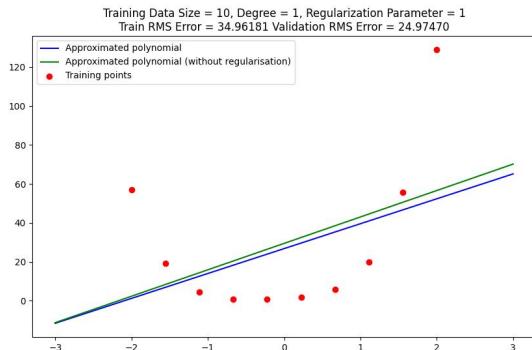

### 1.1.3 Plots of Approximated Functions with Regularization

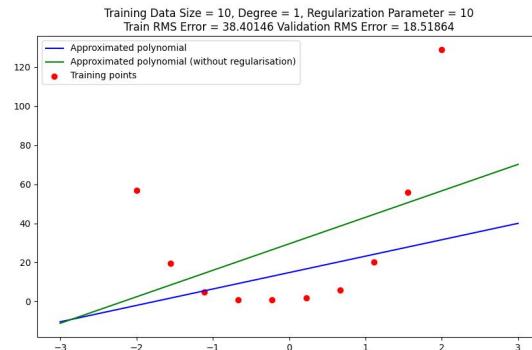

(1)  $m = 1, \lambda = 0.01$

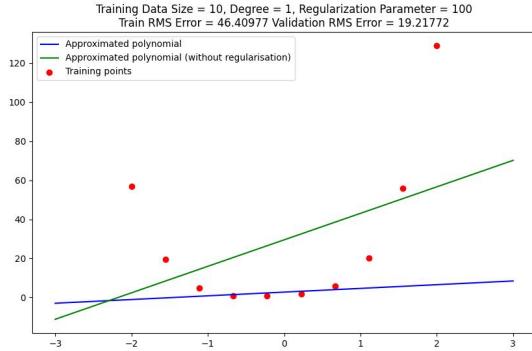

(2)  $m = 1, \lambda = 0.1$

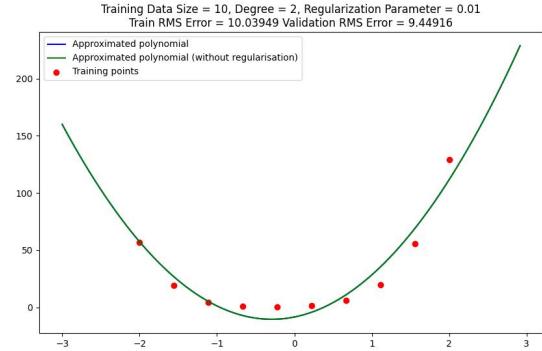

(3)  $m = 1, \lambda = 1$

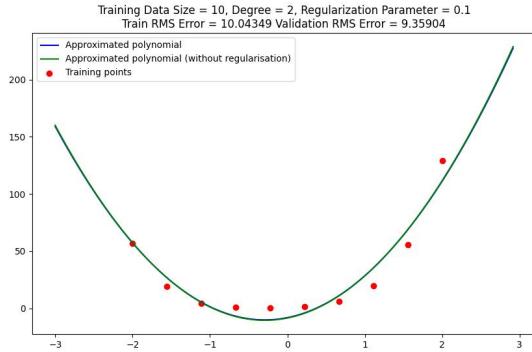

(4)  $m = 1, \lambda = 10$

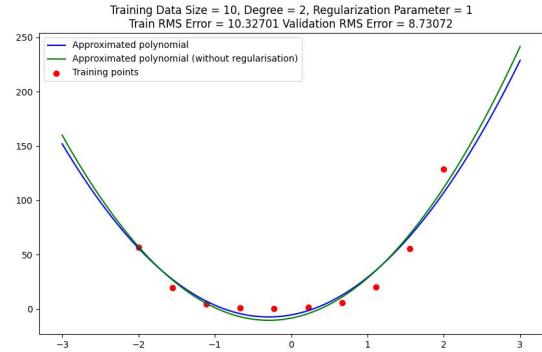

(5)  $m = 1, \lambda = 100$

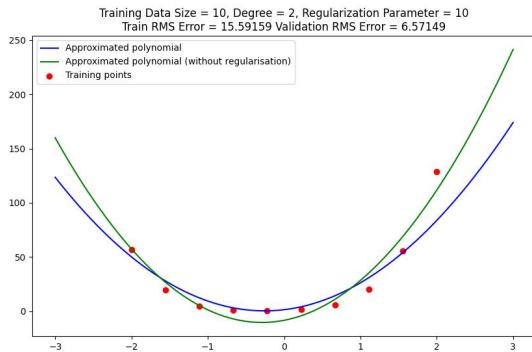

(6)  $m = 2, \lambda = 0.01$

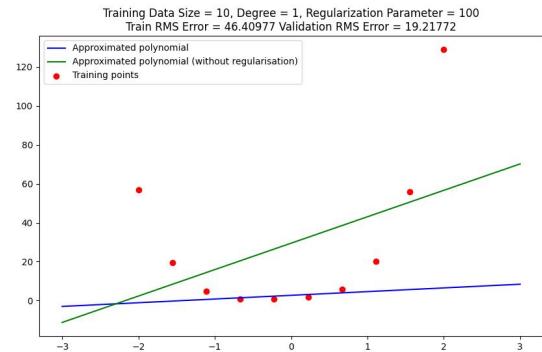

(7)  $m = 2, \lambda = 0.1$

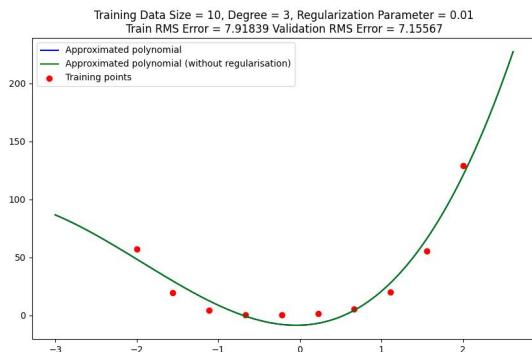

(8)  $m = 2, \lambda = 1$

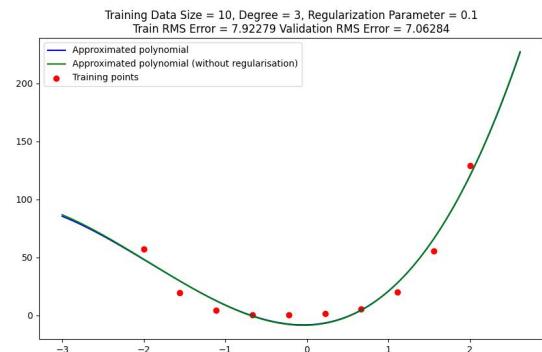

(9)  $m = 2, \lambda = 10$

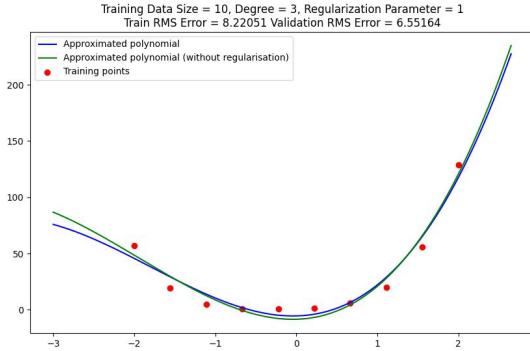

(10)  $m = 2, \lambda = 100$

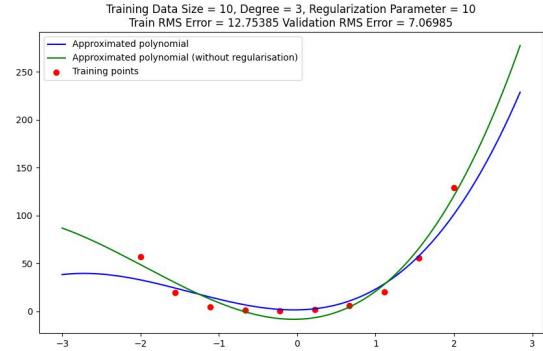

(11)  $m = 3, \lambda = 0.01$

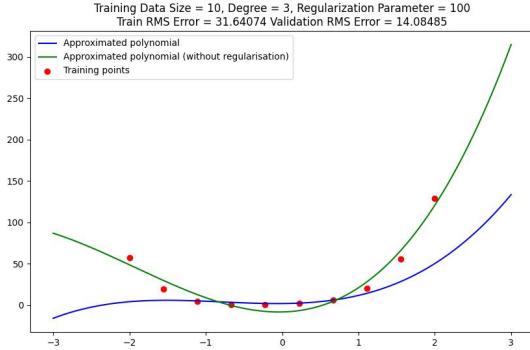

(12)  $m = 3, \lambda = 0.1$

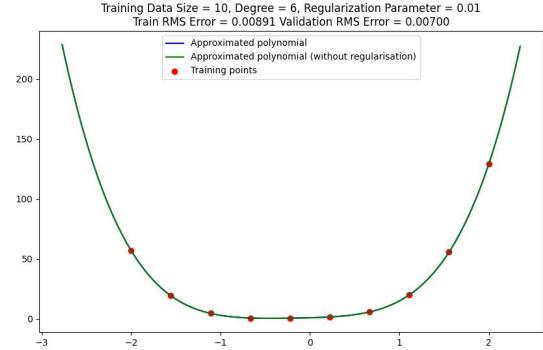

(13)  $m = 3, \lambda = 1$

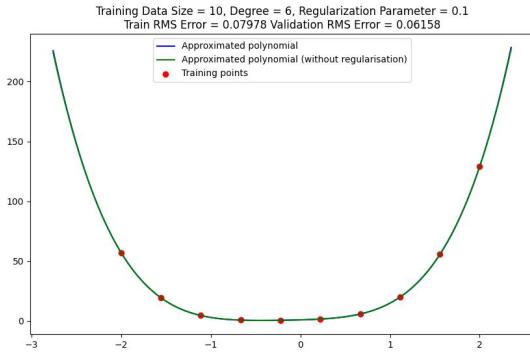

(14)  $m = 3, \lambda = 10$

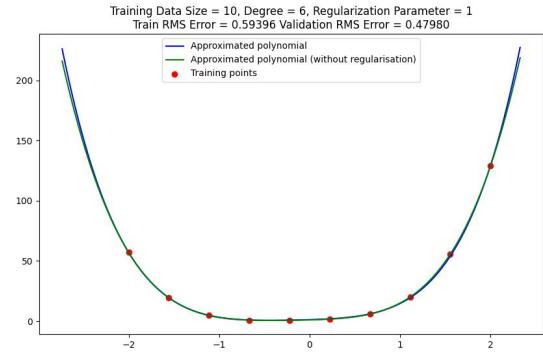

(15)  $m = 3, \lambda = 100$

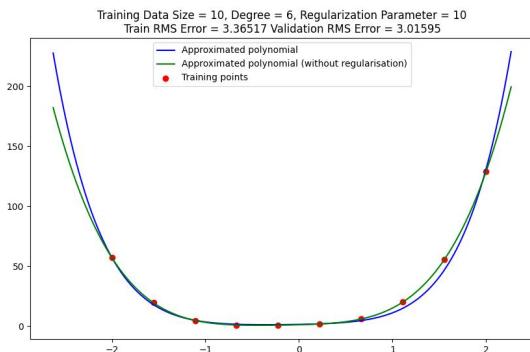

(16)  $m = 6, \lambda = 0.01$

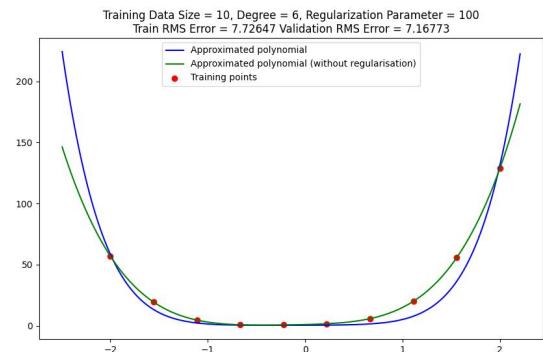

(17)  $m = 6, \lambda = 0.1$

(18)  $m = 6, \lambda = 1$

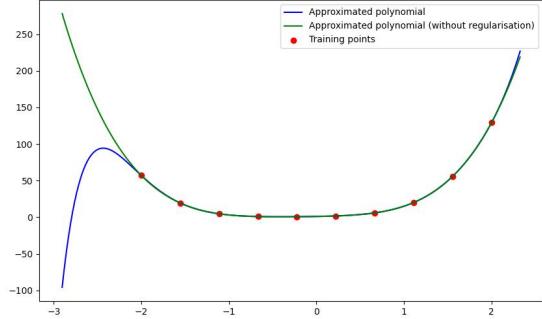

(19)  $m = 6, \lambda = 10$

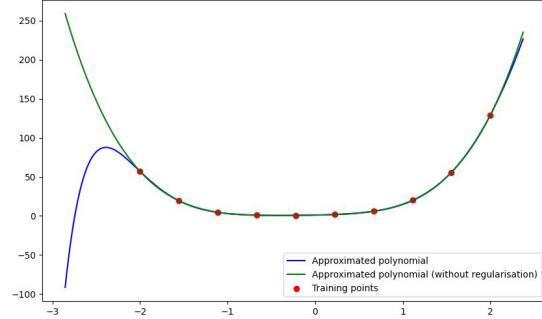

(20)  $m = 6, \lambda = 100$

Training Data Size = 10, Degree = 9, Regularization Parameter = 0.01  
 Train RMS Error = 0.04611 Validation RMS Error = 0.15320

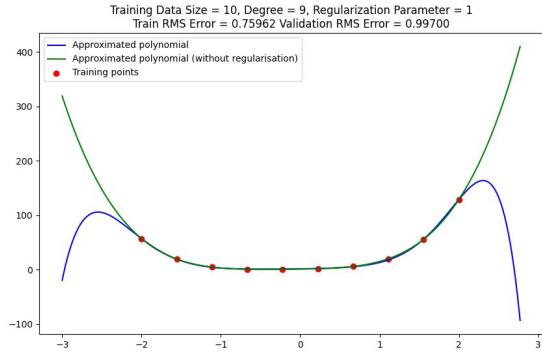

(21)  $m = 9, \lambda = 0.01$

Training Data Size = 10, Degree = 9, Regularization Parameter = 0.1  
 Train RMS Error = 0.16216 Validation RMS Error = 0.27742

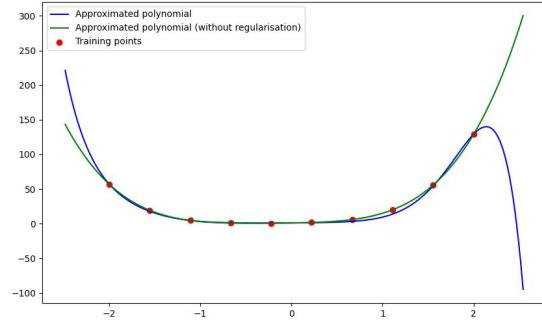

(22)  $m = 9, \lambda = 0.1$

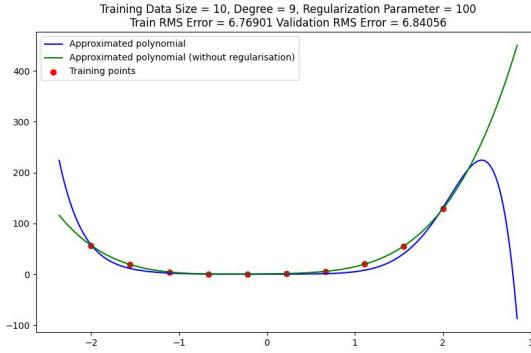

(23)  $m = 9, \lambda = 1$

Training Data Size = 10, Degree = 9, Regularization Parameter = 10  
 Train RMS Error = 2.24021 Validation RMS Error = 2.90231

(24)  $m = 9, \lambda = 10$

(25)  $m = 9, \lambda = 100$

Figure 2: Approximated Functions with Regularization for training dataset of size 10

#### 1.1.4 Inferences

1. For small values of  $m = 1, 2, 3$ , the model is still unable to fit to the underlying data. This is a case of underfitting and regularization will not be of help in these models.
2. For large values of  $m = 6, 9$ , even a small amount of regularization causes the model to deviate a lot from the training data. This can be seen in the marked increase in the training error from  $\lambda = 0$  to  $\lambda = 0.01$  for  $m = 6, 9$ . This is likely due to the extremely small size of the training dataset.
3. For all values of the degree  $m$ , as the regularization parameter  $\lambda$  increases, the training error increases and the validation error decreases.
4. Regularization forces the model to slightly deviate from the training points, hence reducing possible overfitting. However, with large values of  $\lambda$  such as 100.0, the model deviates too much from the training data and does not capture the underlying distribution. This can be seen by the increase in validation error. Hence, large values of  $\lambda$  can lead to underfitting.
5. We can see that the use of regularization did not improve the model's performance, hence proving validity our initial assertion regarding the same.

#### 1.1.5 Hyperparameters v/s Training, Validation and Testing Errors

Degree	Regularization Parameter	Training Error	Validation Error	Testing Error
1	0.0	34.844 62	26.923 51	24.777 53

9	100.0	6.769 01	6.840 56	7.822 74

Table 1: Training, Validation and Testing Errors for different  $m, \lambda$  for training dataset of size 10. The best model for each  $m$  is taken to be the one with the lowest validation error and are shown in boldface.

## 1.2 Training Dataset of size 100

### 1.2.1 Plots of Approximated Functions without Regularization

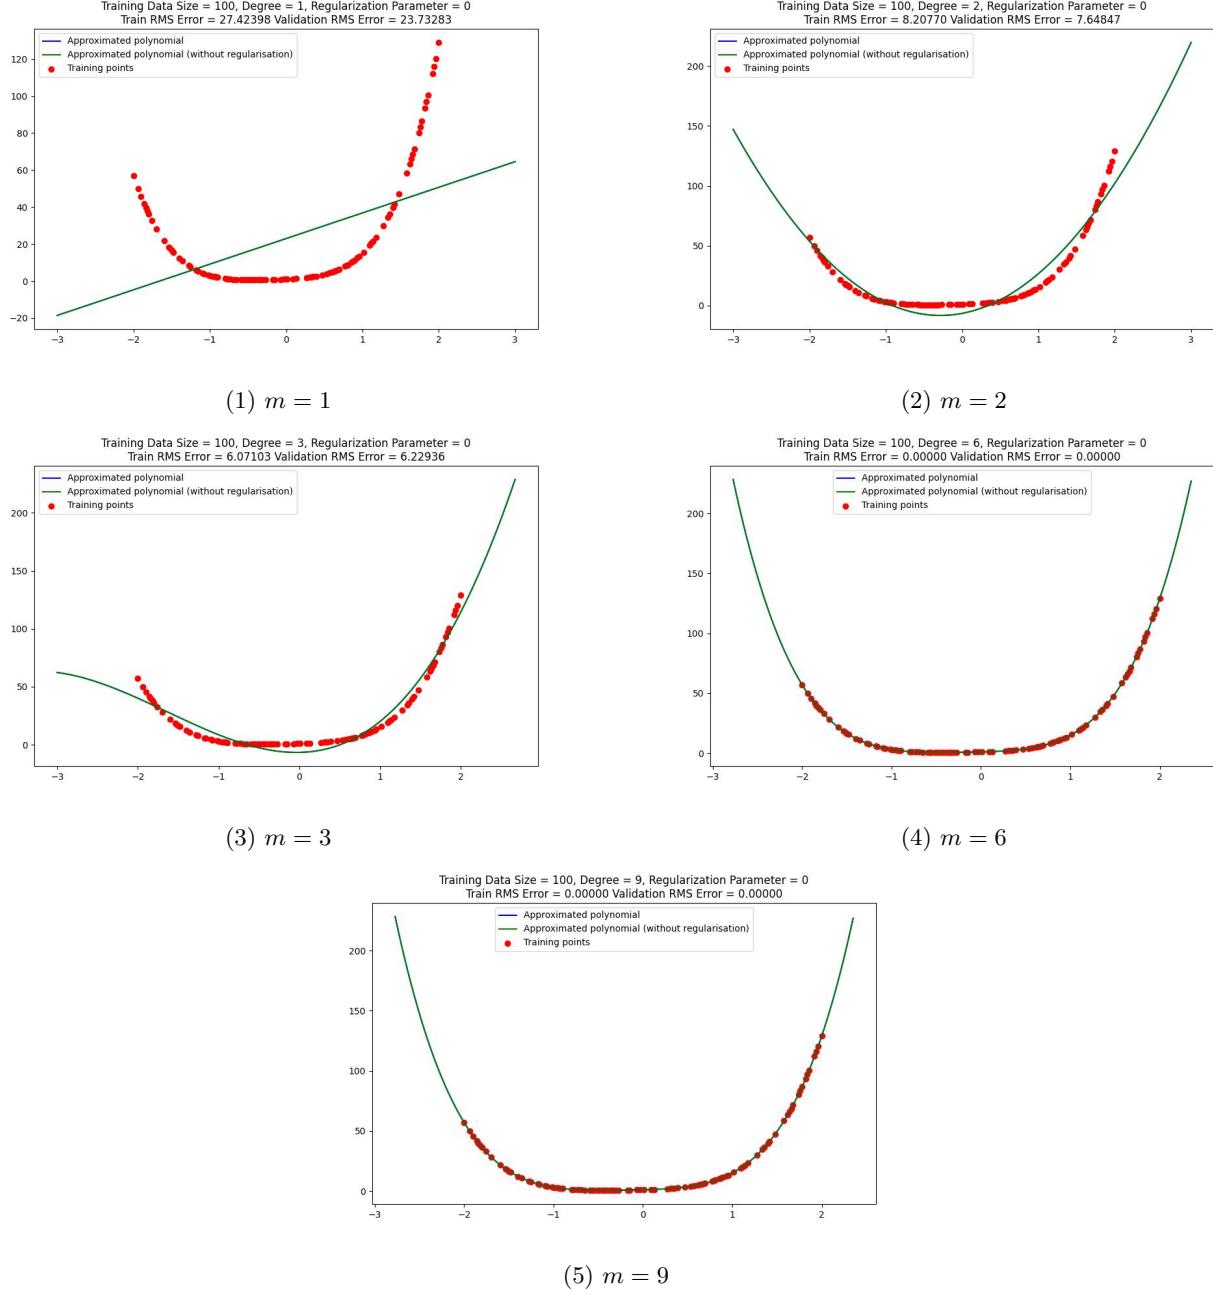

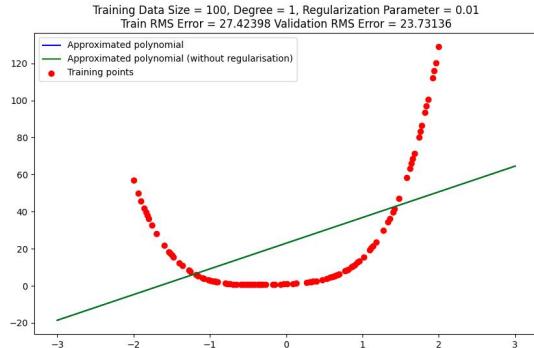

Figure 3: Approximated Functions without Regularization for training dataset of size 100

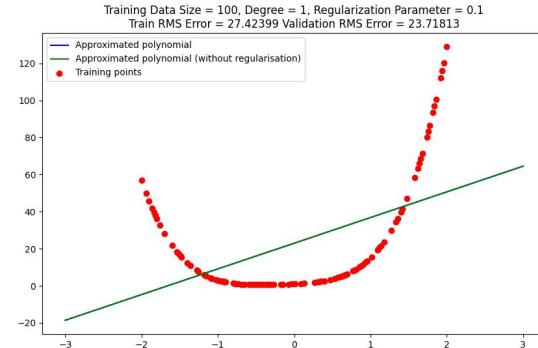

### 1.2.2 Inferences

1. For small values of  $m$  such as 1, 2 and 3, the model does not fit well with the training data and there is underfitting. This is reflected in the high training and validation errors. This indicated that the underlying distribution of data has a much higher complexity than these models.
2. As the model degree increases, the complexity of the model increases and the model fits well with the training data. This is reflected in the lowering of the training and validation errors.
3. However, with higher complexity, the model may overfit with the data. This is reflected in the validation errors for  $m = 6$  and  $m = 9$ , which are  $2.4329 \times 10^{-12}$  and  $1.3962 \times 10^{-10}$  respectively, which is an increase by an order of two.
4. We also find that the performance of the model with  $m = 9$ , has improved by an order of 1 in comparison to the model trained with just 10 data points. This can be attributed to the increase in the size of the training dataset which gives us a better estimation of the model parameters.
5. The best model among these, will be  $m = 6$  as it achieves the least validation error. Since, this model has nearly zero training and testing data, we don't require the use of regularization to improve the model.

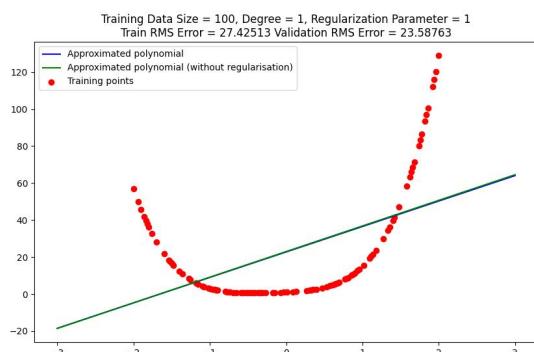

### 1.2.3 Plots of Approximated Functions with Regularization

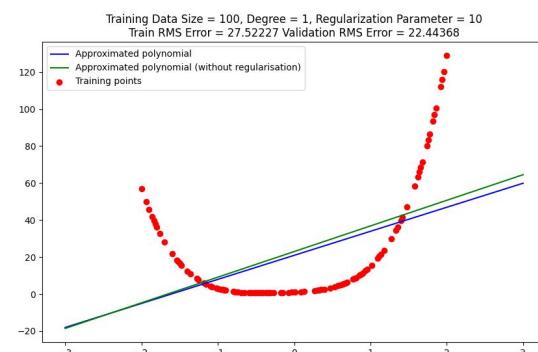

(1)  $m = 1, \lambda = 0.01$

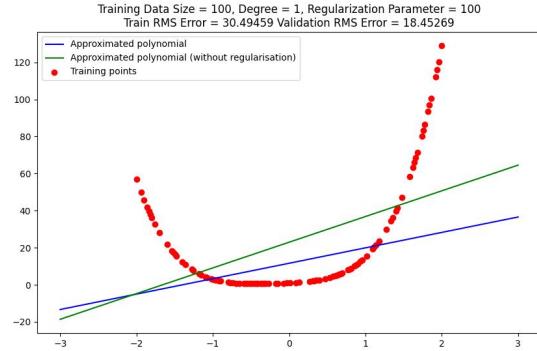

(2)  $m = 1, \lambda = 0.1$

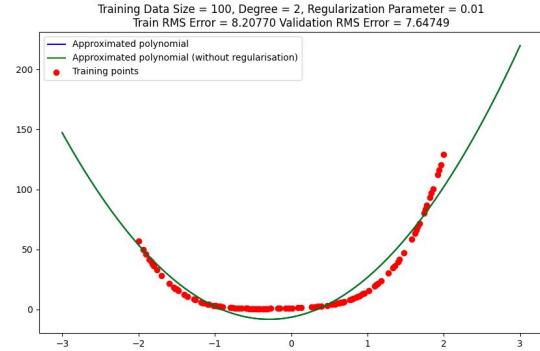

(3)  $m = 1, \lambda = 1$

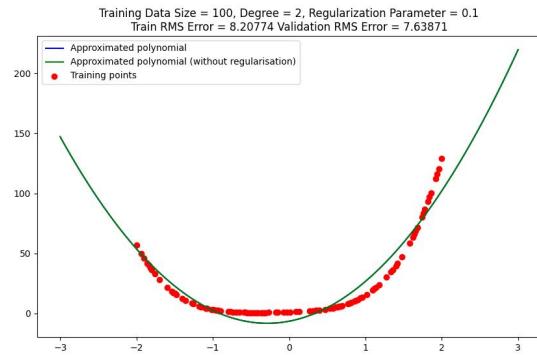

(4)  $m = 1, \lambda = 10$

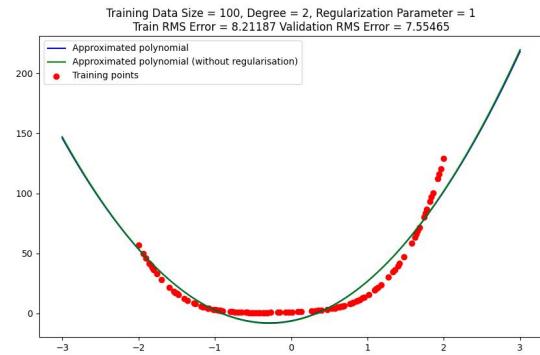

(5)  $m = 1, \lambda = 100$

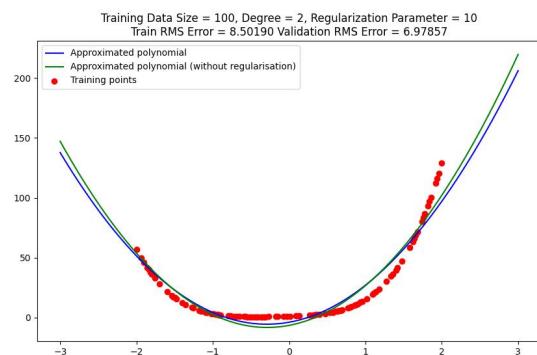

(6)  $m = 2, \lambda = 0.01$

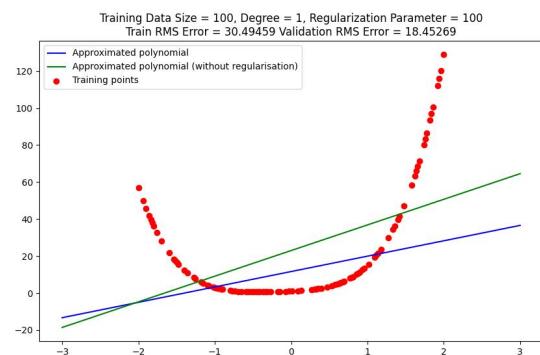

(7)  $m = 2, \lambda = 0.1$

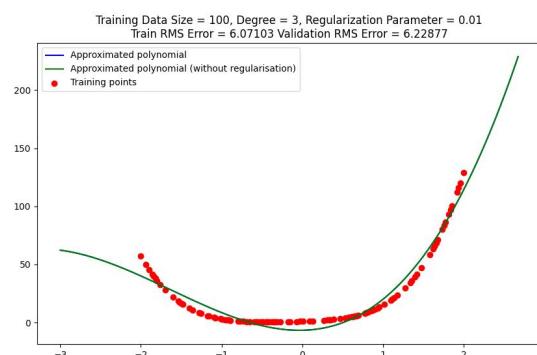

(8)  $m = 2, \lambda = 1$

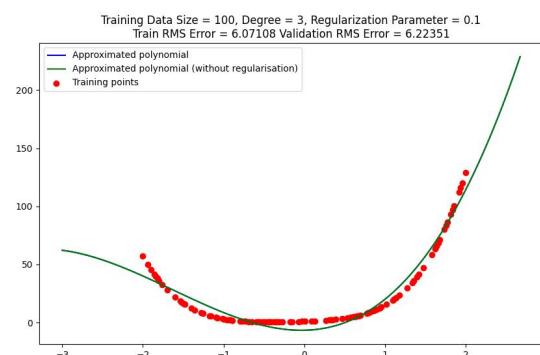

(9)  $m = 2, \lambda = 10$

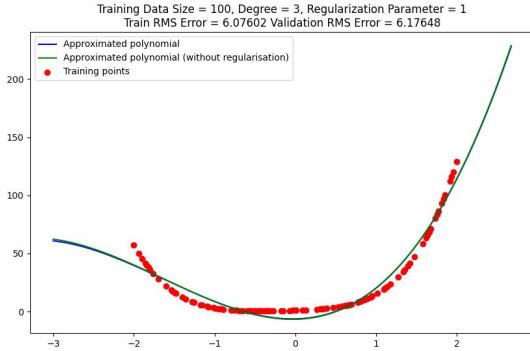

(10)  $m = 2, \lambda = 100$

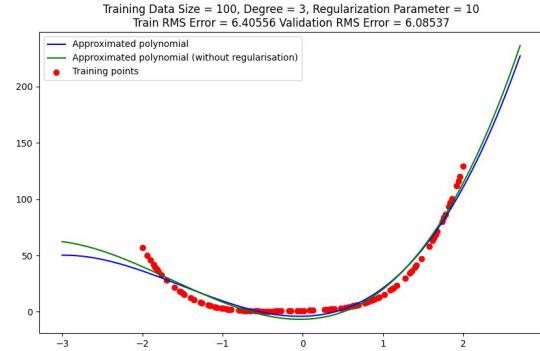

(11)  $m = 3, \lambda = 0.01$

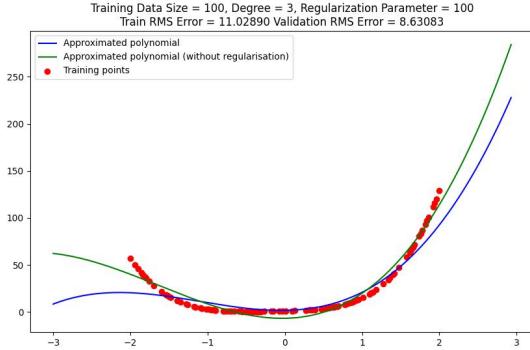

(12)  $m = 3, \lambda = 0.1$

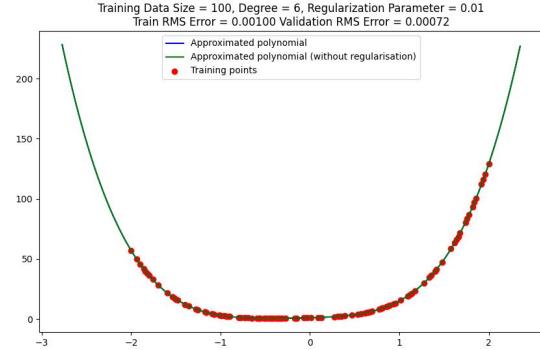

(13)  $m = 3, \lambda = 1$

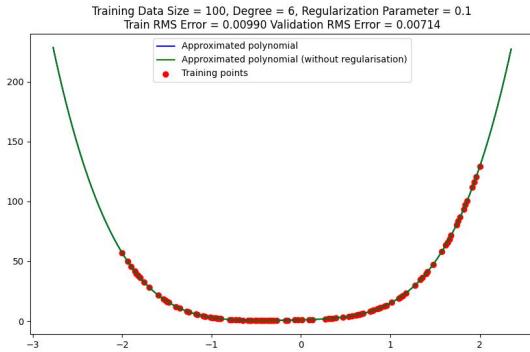

(14)  $m = 3, \lambda = 10$

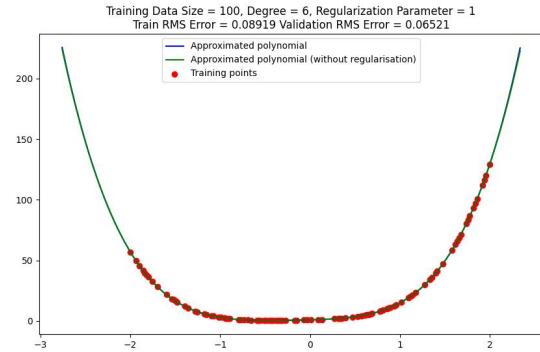

(15)  $m = 3, \lambda = 100$

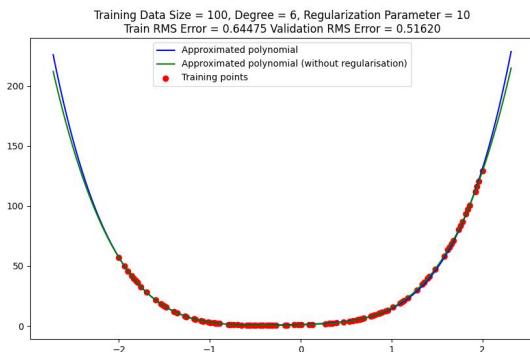

(16)  $m = 6, \lambda = 0.01$

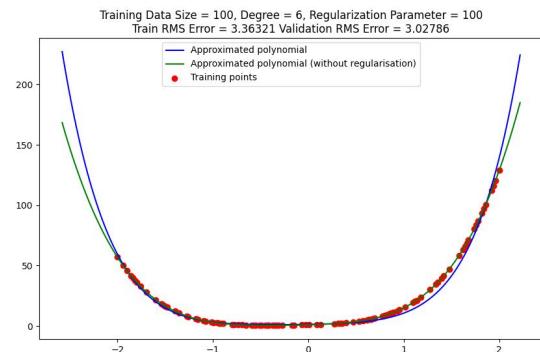

(17)  $m = 6, \lambda = 0.1$

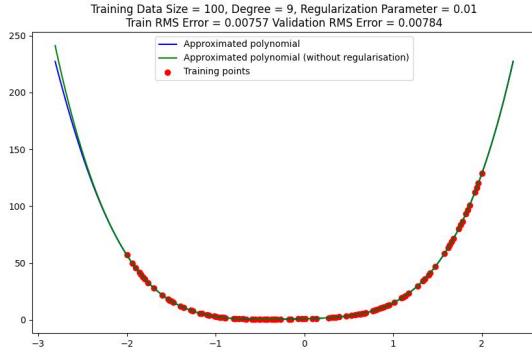

(18)  $m = 6, \lambda = 1$

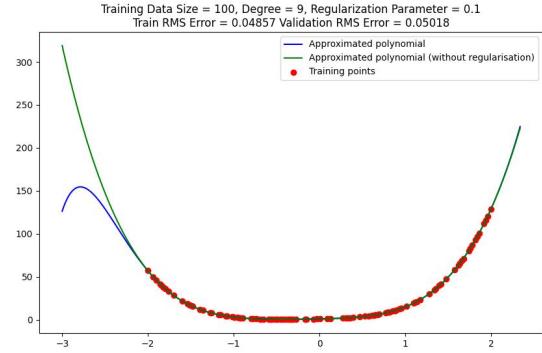

(19)  $m = 6, \lambda = 10$

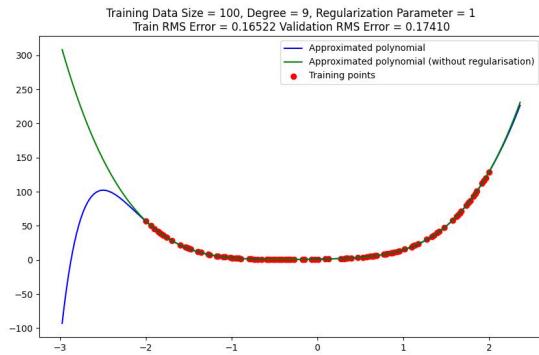

(20)  $m = 6, \lambda = 100$

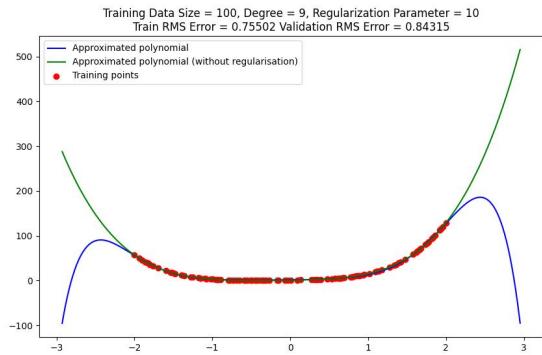

(21)  $m = 9, \lambda = 0.01$

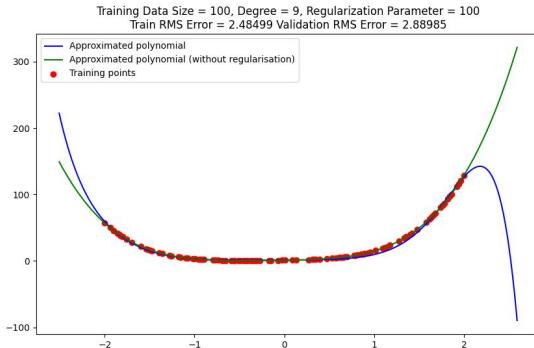

(22)  $m = 9, \lambda = 0.1$

(23)  $m = 9, \lambda = 1$

(24)  $m = 9, \lambda = 10$

(25)  $m = 9, \lambda = 100$

Figure 4: Approximated Functions with Regularization for training dataset of size 100

#### 1.2.4 Inferences

1. The models with  $m = 1, 2, 3$  continue to inadequately fit to the underlying data. This is a case of underfitting and indicates that the data has a much more complex distribution. Regularization is not of help here, as it enhances validation performance at the expense of training performance.
2. In parallel with the training dataset of size 10, as the regularization parameter  $\lambda$  increases, the training error increases and the validation error decreases.
3. As  $\lambda$  increases, it forces the model to slightly deviate from the training points which reduces overfitting. This can also be seen in increasing training error and reducing validation error as  $\lambda$  increases.
4. However when  $\lambda$  is too large, the model begins to deviate too much from the training data and the training and validation errors increase. This can be seen with  $m = 3, 6, 9$  and  $\lambda = 100$ . Hence, large regularization has led to underfitting of the model in these cases.
5. Once again, we see that the use of regularization has not improved the model's performance, proving the validity of our initial assertion.
6. The dataset appears less sensitive to regularization, as varying regularization parameters doesn't significantly affect the model's performance.
7. Higher polynomial degrees (e.g., 9) don't contribute significantly to model improvement. The dataset seems to have a more linear or lower-degree relationship between features and the target variable.
8. The optimal model complexity seems to lie around degree 6, striking a balance between capturing essential patterns and avoiding unnecessary complexity. This suggests that a polynomial of degree 6 adequately represents the underlying structure of the dataset.

### 1.2.5 Hyperparameters v/s Training, Validation and Testing Errors

Degree	Regularization Parameter	Training Error	Validation Error	Testing Error
1	0.0	27.423 98	23.732 83	24.773 74

Table 2: Training, Validation and Testing Errors for different  $m, \lambda$  for training dataset of size 100. The best model is taken to be the one with the lowest validation error and are shown in boldface.

## 2 Task 2: Linear Model for Regression using Polynomial Basis Functions for Dataset 2

### 2.1 Training Dataset of size 50

#### 2.1.1 Surface Plots of Approximated Functions without Regularization

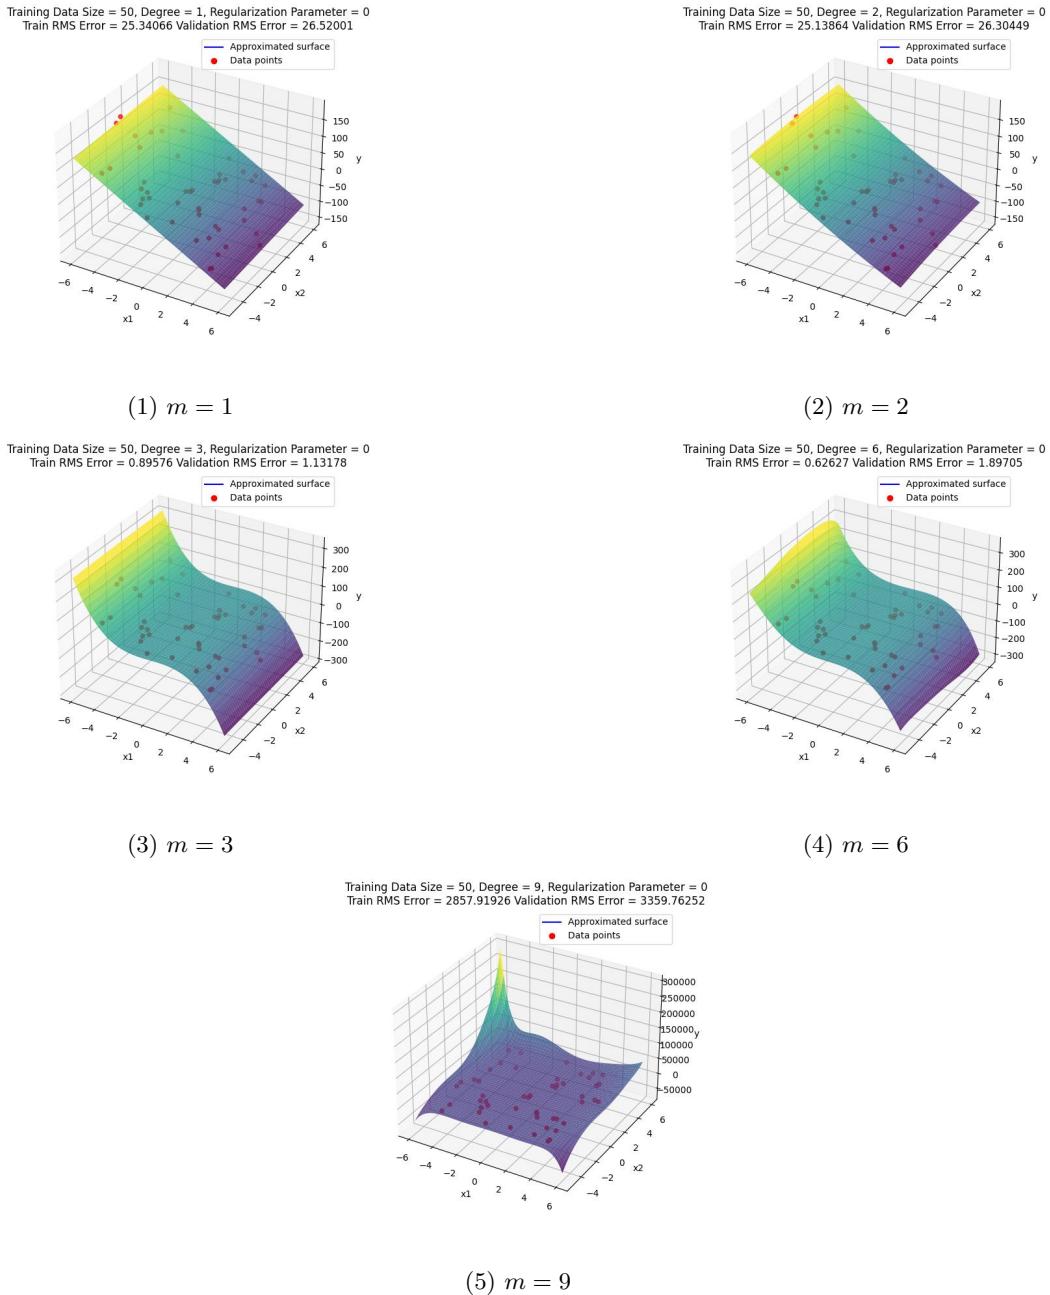

Figure 5: Approximated Functions without Regularization for training dataset of size 50

### 2.1.2 Inferences

1. **Underfitting (Degree 1-2):** For degrees 1 and 2, the model exhibits underfitting with relatively high training and validation losses. These degrees are too simplistic to capture the complexity of the underlying patterns in the data.

2. **Effective Fitting (Degree 3):** Degree 3 performs well, achieving low training loss (0.89) and validation loss (1.13). This indicates an effective balance between model complexity and fitting the data.

The number of parameters ( $D$ ) for degree  $m$  and input dimensionality  $d$  is given by

$$D = \frac{(m+d)!}{m! \cdot d!}.$$

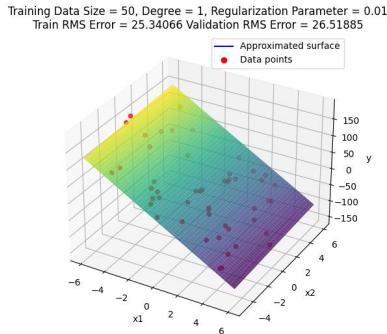

3. **Appropriate Complexity (Degree 6):** Degree 6 shows low training loss (0.62) and a slightly higher validation loss (1.89). The increase in complexity compared to degree 3 is acceptable, and further investigation, such as regularization techniques, could be explored to optimize performance.

4. **Lack of Training Samples (Degree 9):** The extremely high training loss (2857.91) and even higher validation loss (3359.76) for degree 9 indicate that the model is too complex for the limited number of training samples (50). The number of parameters ( $D$ ) for degree  $m = 9$  and input dimensionality  $d = 2$  is given by

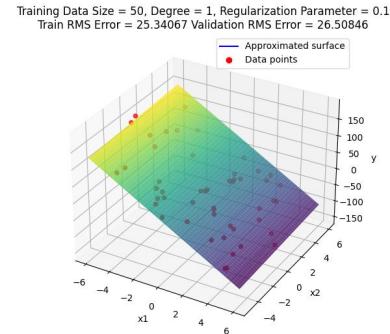

$$D = \frac{(9+2)!}{9! \cdot 2!} = 55.$$

With only 50 samples, the model lacks sufficient data to effectively learn and generalize, resulting in poor performance.

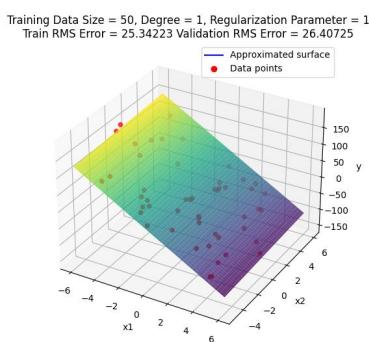

### 2.1.3 Surface Plots of Approximated Functions with Regularization

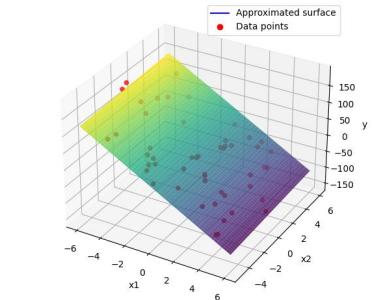

(1)  $m = 1, \lambda = 0.01$

(2)  $m = 1, \lambda = 0.1$

Figure 6: Approximated Functions with Regularization for training dataset of size 50

#### 2.1.4 Inferences

- Degree 1:** As the regularization parameter  $\lambda$  increases, both training and validation errors increase consistently. This aligns with the expected behavior of regularization, which tends to prevent overfitting. The increase in errors indicates a constraint on the model's complexity, preventing it from fitting the training data too closely.
- Degree 2:** Similar to degree 1, increasing  $\lambda$  leads to higher training and validation errors, indicating consistent regularization effects. The model, being of higher degree, exhibits a more pronounced sensitivity to regularization, emphasizing the need for appropriate parameter tuning.
- Degree 3:** For degree 3, the pattern of increasing errors with higher  $\lambda$  continues, but the impact is less severe compared to degrees 1 and 2. This suggests that the model with degree 3 is more robust to regularization, potentially due to its moderate complexity.

4. **Degree 6:** With degree 6, the trend of increasing errors with higher  $\lambda$  persists. The model appears sensitive to regularization, particularly with  $\lambda = 100.0$ . This indicates that, at this level of complexity, too much regularization can negatively impact performance.
5. **Degree 9:** Degree 9 exhibits a distinct behavior. With  $\lambda = 0.0$ , the model has an extremely high training error, suggesting potential underfitting. However, as  $\lambda$  increases, both training and validation errors decrease. This unexpected behaviour could be a result of numerical instability and a lack of input samples to properly train the model.
6. Generally, increasing  $\lambda$  has a regularizing effect, helping to prevent overfitting. However, the impact of regularization varies with the degree of the polynomial and the sample size used to train the model. Polynomial basis functions of degree 3 and 6, tend to have a better overall performance in the train, test and validation dataset.

Train RMS Error = 0.85346 Validation RMS Error = 1.14151

(4)  $m = 6$

Training Data Size = 200, Degree = 9, Regularization Parameter = 0  
Train RMS Error = 0.79632 Validation RMS Error = 1.28779

(5)  $m = 9$

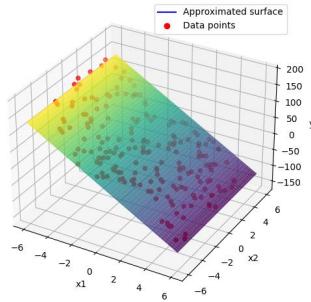

Figure 8: Approximated Functions without Regularization for training dataset of size 200

## 2.2.2 Inferences

1. For Degree 1 and Degree 2, errors are relatively high across all datasets, indicating potential underfitting and suggesting the need for regularization.
2. Degree 3 exhibits a substantial decrease in errors, indicating improved model fit, especially in the testing dataset.
3. Degrees 6 and 9 continue the trend of decreasing errors, showcasing the benefits of higher degrees. Though with higher degree, we face the issue of overfitting.
4. Generally, there is a need for regularization across all degrees to avoid overfitting. Higher degrees (6 and 9) show a risk of overfitting, particularly when regularization is absent.
5. With 200 data points and no regularization, underfitting is not as pronounced, especially in the case of higher degrees like Degree 6 and 9.
6. The larger number of training samples seems to mitigate the underfitting effect, emphasizing the impact of dataset size on regularization outcomes.
7. The models with higher degrees such as  $m = 6, 9$  have much lower training error than validation error. Hence, this may be a case where regularization might improve the generalizability of the model.

(25)  $m = 9, \lambda = 100$

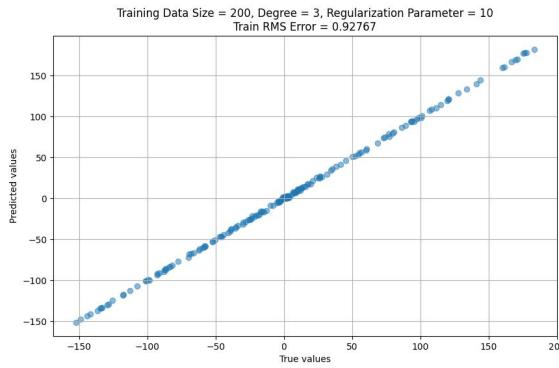

Figure 9: Approximated Functions with Regularization for training dataset of size 200

#### 2.2.4 Inferences

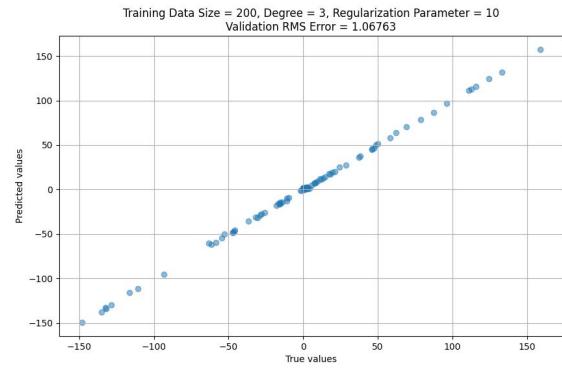

1. Higher degrees generally reduce the training error. But similar to the 50 training sample case, we observe overfitting in these cases.
2. Low degrees  $m = 1, 2$  exhibit underfitting, with validation errors decreasing as regularization increases.
3. For Degree 3, a moderate regularization parameter  $\lambda = 1$  yields good results, but higher degrees show overfitting tendencies.
4. Degrees 6 and 9 follow similar trends, with higher regularization improving performance, but overfitting is more pronounced.
5. Low regularization  $\lambda = 0, 0.01$  leads to high errors due to overfitting in case of higher degrees  $m = 6, 9$ .

6. Moderate regularization  $\lambda = 0.1$ , 1 strikes a balance, preventing overfitting and providing good generalization.
7. High regularization  $\lambda = 10$  is effective, but very high  $\lambda = 100$  leads to underfitting.
8. Underfitting is observed with simple models i.e, low degrees and high regularization.
9. Overfitting is evident with higher degrees and low regularization, leading to a decrease in testing performance.
10. Beyond polynomial degree 6, the performance improvement becomes marginal, suggesting diminishing returns with increasing model complexity.
11. Polynomial degrees 6 and 3 outperform degree 9, indicating an optimal complexity level that balances bias and variance for this dataset.
12. Regularization has improved the performance of the model, thus validating our original assertion about the same.

Table 5: Training, Validation and Testing Errors for different  $K, \sigma, \lambda$  for training dataset of size 50. The best model is taken to be the one with the lowest validation error and are shown in boldface.

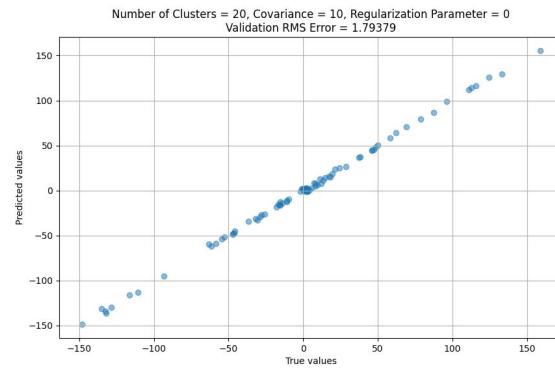

### 3.1.2 Inferences

1. Generally, increasing clusters tends to decrease training errors, possibly leading to overfitting.
2. Configuration with 20 clusters,  $\lambda = 0$ , and covariance of 10 exhibits the least training error at 0.9388. It also performs well on the validation and test data.
3. Increasing regularization parameter  $\lambda$  raises the training and reduces the validation errors. However we observe an increase in the validation error for large values of  $\lambda$  (10, 100).
4. Non-zero  $\lambda = 0.01, 0.1$  values show a decrease in validation errors, suggesting a reduction in overfitting.
5. The number of clusters influences training errors. An increase in clusters generally reduces the errors.
6. Configuration with  $\lambda = 100$  consistently shows higher errors across all datasets, indicating potential oversensitivity to regularization.
7. The error is also dependent on covariance. A general observed trend is that the error drops as the covariance increases. But above a certain threshold, the error starts rising with a rise in covariance. The optimal value of covariance depends on number of clusters chosen for the data. Typically, we can observe a moderate value of covariance  $\sigma = 10, 15$ , which seems to be the optimal value.
8. The model has roughly similar performance on train, test and validation data, given that the optimal parameters are chosen.
9. The model performs optimally with  $\lambda = 0$ , covariance = 10, and 20 clusters.

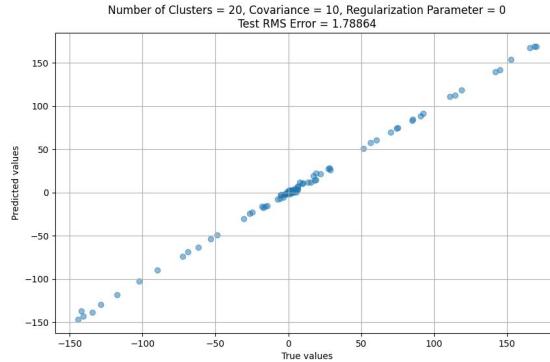

### 3.1.3 Scatter Plots of the Best Model

(1) Best model ( $K = 20, \sigma = 10, \lambda = 0$ ) performance in Training Data

(2) Best model ( $K = 20, \sigma = 10, \lambda = 0$ ) performance in Validation Data

(3) Best model ( $K = 20, \sigma = 10, \lambda = 0$ ) performance in Testing Data

Table 6: Training, Validation and Testing Errors for different  $K, \sigma, \lambda$  for training dataset 2 of size 200. The best model is taken to be the one with the lowest validation error and are shown in boldface.

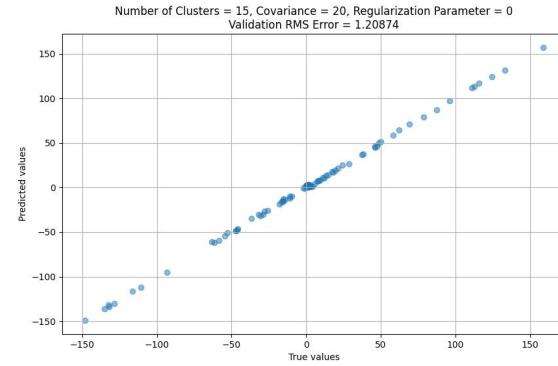

### 3.2.2 Inferences

1. Increasing the number of clusters generally reduces training errors but can lead to overfitting.
2. Effect of regularization on the errors is similar to what was observed in case of 50 data points.
3. With 200 samples, the model consistently exhibits a similar magnitude of the training and validation errors, indicating less overfitting and generalization.
4. The relation between covariance and model performance is similar to the case of 50 sample test inputs. Here a moderate covariance value of  $\sigma = 15$ , seems to be the optimal value for different cluster sizes.
5. The model has a similar performance on the training, validation and testing data when optimal parameters are chosen.
6. The model performs optimally with  $\lambda = 0$ , covariance = 20, and 15 clusters.
7. The dataset exhibits resilience against overfitting, as evidenced by the optimal configuration's preference for a regularization parameter of 0. This suggests that the model generalizes well without the need for strong regularization
8. The model's performance appears to be sensitive to changes in covariance values. The fact that the optimal configuration includes a covariance of 10 indicates that the dataset responds favorably to a moderate level of covariance.

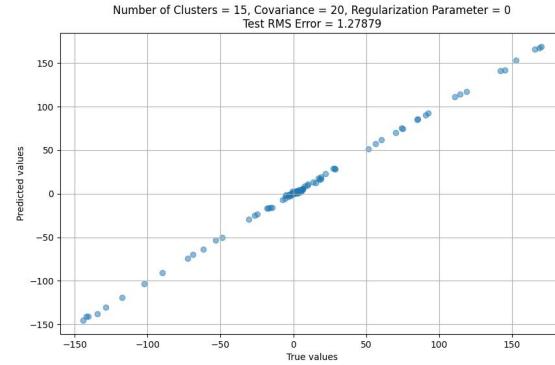

### 3.2.3 Scatter Plots of the Best Model

(1) Best model ( $K = 15, \sigma = 20, \lambda = 0$ ) performance in Training Data

(2) Best model ( $K = 15, \sigma = 20, \lambda = 0$ ) performance in Validation Data

(3) Best model ( $K = 15, \sigma = 20, \lambda = 0$ ) performance in Testing Data

Table 7: Training, Validation and Testing Errors for different  $K, \sigma, \lambda$  for training dataset 2 of size 274. The best model is taken to be the one with the lowest validation error and are shown in boldface.

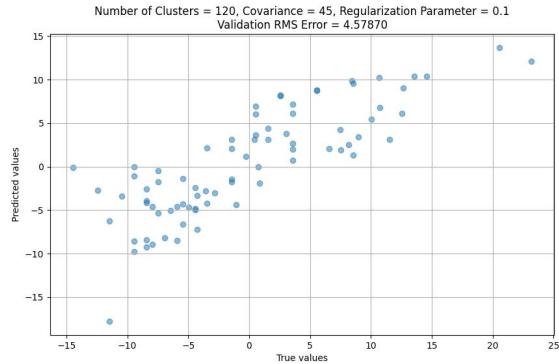

## 4.2 Inferences

1. Higher  $\lambda$  values lead to increased training errors. Validation and testing errors similarly rise with higher  $\lambda$ .
2. Increasing regularization leads to higher errors ( $\lambda = 100$ , generally has large errors for all the datasets).
3. Changes in covariance can affect errors. We can roughly observe that increasing covariance reduces the errors.
4. Higher cluster counts tend to reduce training errors; e.g., higher counts like 70 or 80 clusters exhibit lower training errors. However, higher cluster counts, as seen in the 120 clusters, 40 covariance, and regularization parameter 0 configuration, might lead to overfitting.
5. The model has roughly similar performance on the training, validation and testing data when optimal hyperparameters are chosen.
6. Model with 120 clusters, 45 covariance, and regularization parameter 0.1 performs optimally with both training and validation datasets.
7. The dataset exhibits sensitivity to regularization, emphasizing the importance of controlling model complexity to avoid overfitting.
8. Higher cluster counts (e.g., 120 clusters) contribute to improved model performance, suggesting that the underlying patterns in the dataset benefit from a more intricate representation.
9. The dataset benefits from a higher covariance (45), indicating that a broader spread of data is essential for capturing the nuanced relationships within the dataset.

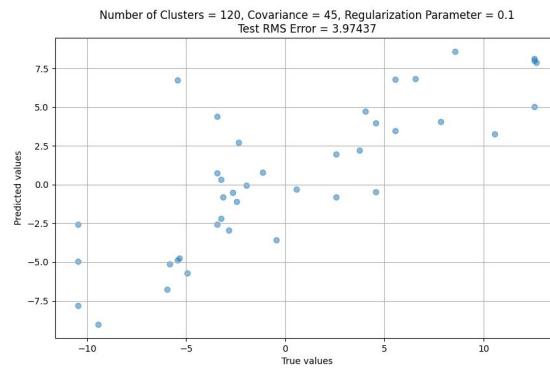

### 4.3 Scatter Plots of the Best Model

(1) Best model ( $K = 120, \sigma = 45, \lambda = 0.1$ ) performance in Training Data

(2) Best model ( $K = 120, \sigma = 45, \lambda = 0.1$ ) performance in Validation Data

(3) Best model ( $K = 120, \sigma = 45, \lambda = 0.1$ ) performance in Testing Data

Figure 13: Best model performance with Training, Validation and Testing Data

## 5 Task 4: Linear Model for Regression using Polynomial Basis Functions for Dataset 4

### 5.1 Description of Dataset

We have chosen the **California Real Estate Dataset**. The input features pertain to several features of the a typical house in a Californian district, which are listed below and an output feature that is the median housing value in that Californian district. The entire dataset has a total of 17,000 data points. The random sample of 500 data points were chosen for the purpose of this assignment. Out of this, 60% of the data was taken for the training split, 20% for the validation split and 20% for the testing split.

#### Input Features:

1. Latitude
2. Longitude
3. Median Housing Age
4. Total Rooms
5. Total Bedrooms
6. Population
7. Number of households
8. Median Income

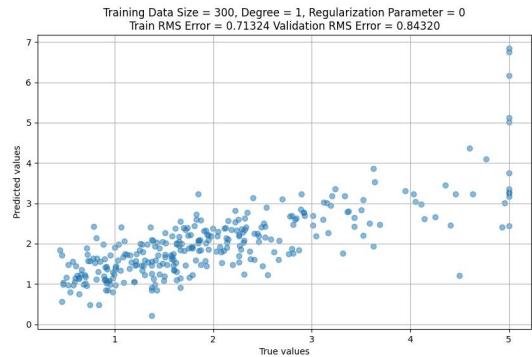

#### Output Feature:

1. Median House Value

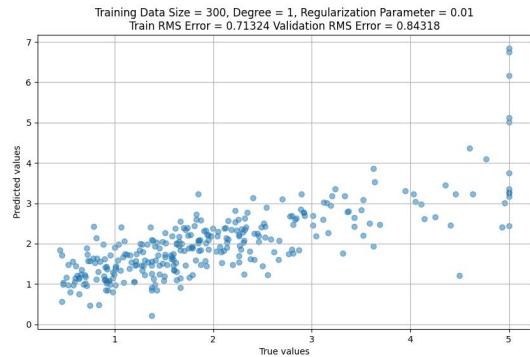

### 5.2 Procedure

- We performed a linear regression using polynomial basis functions for the dataset.
- The input features have varying scales and hence each feature was divided by a factor to make all the data similar in scale.
- Several different combinations of the degree of the polynomial,  $m = 1, 2, 3, 4, 5, 8$ , and the regularization parameter,  $\lambda = 0, 0.01, 0.1, 1, 10, 100$  were tested.
- The model was trained on the training data and tested using validation data.
- The best model was chosen using the Cross-Validation method and the final model was tested on the testing data.
- All findings are detailed below.

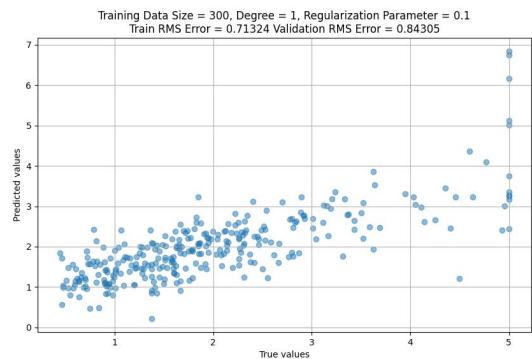

### 5.3 Scatter Plots of Approximated Functions

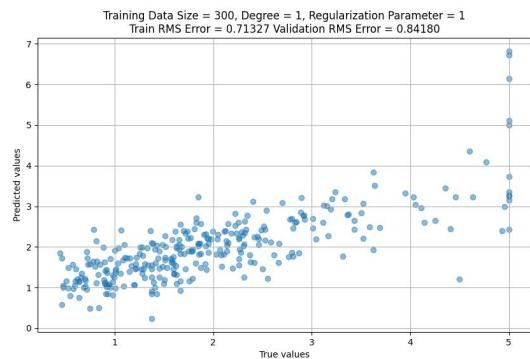

(1)  $m = 1, \lambda = 0$

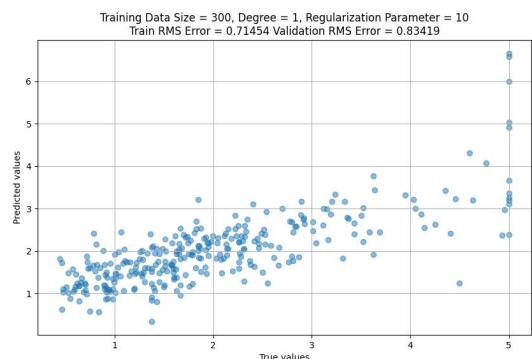

(2)  $m = 1, \lambda = 0.01$

(35)  $m = 8, \lambda = 10$

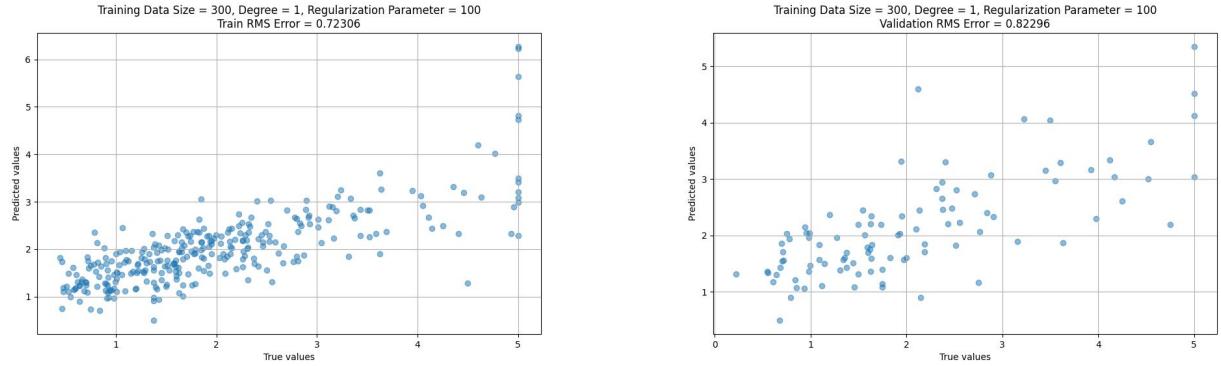

(36)  $m = 8, \lambda = 100$

Figure 14: Scatter Plots of Approximated Functions for different  $m, \lambda$

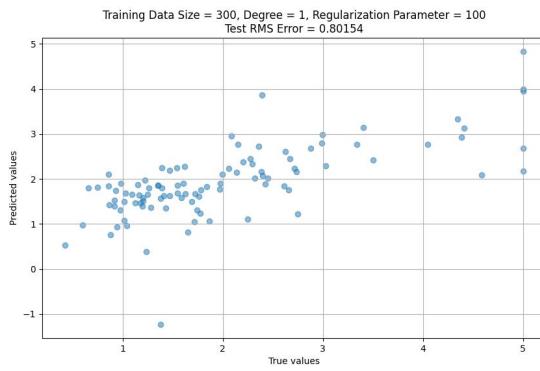

## 5.4 Inferences

- For  $m = 1$ , the model fits well with the training data and also performs well with the validation data.
- With regularization, the model performance on the validation data further increases with minimal drop in performance in the training data.
- As the degree increases, the model begins to overfit on the training data. This can be seen with the decrease in the training error and increase in the validation error.
- At degree  $m = 4$ , with no regularization the model has the lowest training error, but the validation error is huge.
- The validation error improves with the usage of regularization but the model, still, is highly overfitted on the training data.
- For degrees,  $m = 5, 8$  the model begins to fall apart and both the training and validation errors shoot up. This is due to the insufficient number of samples for the training of the model. For  $m = 5$ , we require atleast 462 samples and for  $m = 8$ , we require atleast 3003 samples for a good approximation. These values are given by equation (1).
- The best model is identified to be one with parameters of  $m = 1, \lambda = 100$ .

## 5.5 Scatter Plots of the Best Model

(1) Best model ( $m = 1, \lambda = 100$ ) performance in Training Data    (2) Best model ( $m = 1, \lambda = 100$ ) performance in Validation Data

(1) Best model ( $m = 1, \lambda = 100$ ) performance in Testing Data

Figure 15: Best model performance with Training, Validation and Testing Data

## 5.6 Inferences

1. The model has similar errors for training, validation and testing data. This shows that the model has not overfitted with the training data and is generalizable.
2. The usage of regularization has improved the performance of the model marginally. The training error has increased by 0.00982 while the validation error has reduced by 0.02024.
3. So, the usage of regularization is not necessary in this situation.
4. High errors on validation and testing datasets when higher degrees are used, even with regularization, suggest a substantial overfitting problem. The model struggles to generalize to unseen data when larger degree polynomials are chosen  $m = 4, 5, 8$ .
5. The observed increase in errors with higher polynomial degrees indicates that the dataset might not have complex relationships that require a polynomial of higher degree. Overfitting becomes more pronounced as the model tries to fit noise in the data.
6. The fact that the best performance is observed with a high regularization parameter (100) suggests that the dataset is particularly sensitive to overfitting. Strong regularization is required to control model complexity and prevent fitting noise.
7. The observed trend of increasing errors with higher degrees and the necessity for strong regularization implies that the dataset may have inherent noise or is inherently less complex.

## 5.7 Hyperparameters v/s Training, Validation and Testing Errors

Table 8: Training, Validation and Testing Errors for different  $m, \lambda$  for training dataset of size 200. The best model is taken to be the one with the lowest validation error and are shown in boldface.
